To analyse our experience with surgical treatment of tricuspid insufficiency (TI) in patients with hypertrophic cardiomyopathy (HCM) and to evaluate the mortality in this group of patients. Between July 1995 and January 2002, 18 patients (14 males and 4 females) with a mean age of 59 years (range 45-80) underwent tricuspid valve repair or tricuspid valve replacement (TVR) due to TI. Preoperative echocardiography revealed trivial or mild TI in 11 cases (61%), moderate TI in 4 cases (22%) and severe TI in 3 cases (17%). The echocardiography findings were confirmed intraoperatively in all cases. One patient had a history of arterial hypertension. No other significant risk factors were present. The mitral valve was normal in all cases. The tricuspid valve consisted of one or two (in 17 cases) separate leaflets. The tricuspid annulus and the right ventricular outflow tract were normal in 13 cases. The size of the tricuspid annulus ranged between 19-29 mm (mean 24 mm). Tricuspid insufficiency was secondary to annular dilatation in 11 cases (61%) and secondary to an enlarged right ventricular outflow tract in 7 cases (39%). One patient had a TVR due to a tricuspid valve malfunction. The tricuspid valve was replaced in 10 cases (56%) and the tricuspid valve was repaired in 8 cases (44%). All patients were examined by postoperative echocardiography on day 0, 1, 2, 3 and 6 months. Ten patients (56%) had a history of preoperative atrial fibrillation. One patient had a history of coronary artery disease and one patient had a history of coronary artery bypass surgery. All patients were discharged from
